

Tissue typing for potential family stem cell or bone marrow donors

Bone Marrow Transplant Unit
Information for patients

Produced: Mar 2022
Review: Mar 2025
Leaflet number: 541 Version: 6

Introduction

If you are reading this leaflet, your family member has been diagnosed with a serious blood disorder, and their doctors feel that a bone marrow or stem cell transplant may help him or her. In these cases it is usual for the doctors to ask the patient's family if they would be willing to have blood samples taken to see if they might be suitable donors. This can be done here in the hospital where the patient is being treated or, if you live out of the area, at your GP practice.

It is important to read this leaflet and understand the implications of giving a blood sample before you make an appointment. If you attend to have the blood test we will assume that you are willing to be a donor for your family member.

All information you give us will be treated in the strictest confidence.

Why do I need this blood test?

The blood test will tell us your tissue type. For a transplant to take place, your tissue type needs to match that of your family member. Matching is based on your human leukocyte antigen (HLA) tissue type. Your HLA is part of what makes you 'you' – your individual genetic characteristics.

Your sample of blood will only be compared with your relative's blood and will not be tested for compatibility with anyone else.

Where do we get our individual tissue types from?

Tissue types are inherited from our parents. These can combine in many different ways. This means that there are millions of different tissue types. However, if a person inherits the same HLA combination from their parents, they could be a suitable donor for a sibling.

If a close HLA match cannot be found, then a haploidentical (haplo) transplant maybe an option. A haplo tansplant uses a family member whose tissue type is half-matched to yours. Children are always a half-match for their biological parents, and vice versa. Siblings have a 50% chance of being a half-match for each other.

It is important to point out that if you are the same blood group as your family member, this does not mean that you will be a suitable match. In fact, you could have a different blood group to your family member and still be a suitable match.

Why is tissue type important in transplantation?

If the tissue types of the donor and the patient are carefully matched, this will give the greatest chance of the transplantation being successful. If the tissue types are identical this will reduce the risk of rejection. The doctors will consider which is best for the patient: a full sibling match (if there is one), a donor match (from outside the family) or a haplo match.

What are my chances of being a suitable match?

You have a 1 in 4 chance of being an identical match with one of your full siblings. However, if you are a half-sibling you will not be a match.

In some families, more than one sibling can be a suitable HLA match. Therefore, more than one sibling could be a suitable match to donate bone marrow or stem cells. In this situation, a decision will be made about who will be the most suitable donor to use.

With haplo matches most parents, children and siblings of the patient are matches.

Do I have to be in good health to be a donor?

Yes, there are strict rules that mean that if you have certain health problems you cannot be a donor. In that case it would not be worth having the test done.

Do you have, or have you had:

Cancer of any form	Yes / No
Serious heart disease	Yes / No
A stroke	Yes / No
Epilepsy	Yes / No
Problems with your bone marrow or immune system	Yes / No
HIV, Hepatitis, TB infection	Yes / No
Are you currently being treated for any medical condition?	Yes / No
Have you ever been told that you cannot give blood?	Yes / No

Frequently asked questions

When do I get the results?

The results of the test are usually available after two to four weeks, and we will write to you with the results.

What happens if I am not a match?

If none of the patient's siblings is a match, it may be possible for us to find an unrelated donor from international registers of potential donors or consider haplo matches.

What happens next if I am a match?

You will be invited to attend an appointment at the hospital. At this appointment you will be counselled to make sure that you are aware of the implications of donation to both you and your family member. Once you have had all your questions answered you will be asked to sign a consent form to confirm that you are happy to proceed with the donation process.

Whilst you are at the clinic, we will assess your general health by performing a detailed examination and doing various tests, including blood tests, X-rays and an ECG (heart tracing).

Within 28 days of this appointment you will be asked to attend for a procedure to collect either your bone marrow or stem cells.

How are bone marrow or stem cells collected?

There are two ways of collecting cells from adult donors: a **peripheral blood stem cell collection** or a **bone marrow collection**. Both procedures are done as day cases.

What is peripheral blood stem cell collection?

Before the stem cell collection takes place, you will be given five daily injections of a growth factor called G-CSF. This helps the stem cells to leave the bone marrow, where they are made, and circulate in the blood stream.

Stem cell collection is carried out using a cell-separating machine. The procedure takes between three and four hours.

What is bone marrow collection?

This is performed under a general anaesthetic (whilst you are asleep). The bone marrow will be taken from the back of your pelvis.

The above information about bone marrow and stem cell collection is very brief. If you would like more detailed information, please ask.

Regulation of transplantation

Transplantation is a carefully regulated process, and all transplant units must be licensed by the Human Tissue Authority (HTA). Further information is available on the HTA website:
